

PREFACE

National Statistical Commission constituted a committee under the Chairmanship of Prof. R. Radhakrishna on pooling of central and state samples of National Sample Surveys (NSS) to identify the preconditions for pooling of central and state sample NSS data and to suggest appropriate methodology for pooling the data to bridge the data gaps and in turn strengthen the database for decentralized planning and governance.

Directorate of Economics and Statistics (DES), J&K has already released the report on pooling of state and central samples of NSS 67th Round. This time again DES, J&K has taken part in the pooling exercise of NSS 69th round.

This report focused on the Poolability testing and analysis of pooled data extracted from Schedule 1.2 of NSS 69th round for certain parameters e.g average floor area, type of structure, tenurial status, drinking water facility, bathroom facility etc.

The present report is focussed on the Poolability & closeness of estimates of validated data of central & state samples as well as their reliability in terms of Relative Standard Error (RSE).

This report has been prepared by Ms. Priyanka Parihar, Assistant Director, Inderjeet Singh, Statistical Officer and Tejbir Singh, Junior Statistical Assistant. The technical assistance provided by National Sample Office, Government of India is acknowledged with special gratitude.

Comments and valuable suggestions from the Researchers and Scholars on this report are most welcome.

CHAPTER-ONE

CHAPTER-1

INTRODUCTION

Background

The National Statistical Commission constituted a committee under the Chairmanship of Dr. R. Radha krishna on Pooling of Central and State samples of National Sample Surveys (NSS) to identify the preconditions for pooling of Central and State sample NSS data and to suggest appropriate methodology for pooling the data to bridge the data gaps and in turn strengthen the database for decentralized planning and governance. The National Statistical Commission in its report has indicated the importance of pooling in the statement: “the statistical agencies of different State governments have been participating in the NSS programme and canvassing the same questionnaires in matched samples of households in their respective States following identical concepts, definitions and procedures. Results from the central samples and state samples have occasionally been compared. The main purpose of the programme is to pool the two samples and obtain dependable estimates for regions within the States”. The Commission recommended: “The State sample data should be processed regularly within a reasonable time after the completion of fieldwork and attempts should be made to obtain and utilize pooled estimates by combining central and state samples”.

Main Objectives of Pooling

The main objective of pooling of central and state sample data is to provide a mechanism by which sample size will be increased and the pooling of the two sets of data would enable better estimates at lower sub state level, particularly at district level. At the State level, this will result in increased precision of the estimates and at disaggregated level, estimates will be more stable. But the major benefit will be derived in the case of estimates generated at sub-state level like NSS region/districts.

Poolability Test of central and state sample

Though the central sample and state sample are drawn independently following identical sampling design with same concepts, definitions and instructions to collect the state sample data but due to lack of adequate training of field and processing staff of State/UTs, the data files in some cases are not properly validated. There is also expected agency bias in the two sets of data generated by different agencies. As such they cannot be merged for generating pooled estimate. Therefore, one needs to test that the samples are coming from identical distribution function. Since the parametric distribution of the sample mean is unknown one may adopt non-parametric tests such as K-S test,

Wald Wolfowitz run Test, Median test etc to test that the samples are coming from identical distribution function. For overall test, we have used the Poolability software supplied by NSSO (MOSPI). In this report we have also calculated the Errors (SE) and Relative standard Errors (RSE) for checking the percentage of standard errors and its deviation from central point.

SE is usually estimated by dividing the population standard deviation by the square root of the sample size (if, population SD is unknown then sample standard deviation is used). The RSE is simply the standard error divided by the mean of the sample. After getting the value of RSE for Urban and rural sectors of state and central level data we need also to calculate RSE of pooled estimate to check the percentage of error which is likely to occur at the time of pooling.

Methodology of pooling

Two alternate methods are used in pooling the central and state sample data.

- a) **Weighting by Matching ratio:** Building aggregate estimate of pooled sample in proportion matching ratio m:n of central and state sample aggregate estimate where m and n are the allotted sample for central and state sample separately for rural and urban sector. Building ratio estimate of pooled sample as ratio of aggregate estimates.
- b) **Weighting by inverse of variance:** Ratio estimates are built by weighting the ratio estimate of central and state sample in proportion to inverse of variance of ratio of the central and state sample.

Sample size of J&K: Total sample size of J&K state for central and state sample are given below:

| J&K –Rural | | | |
|-----------------------|---------------------------|---------------------|---------------------------|
| Central sample | | State sample | |
| FSUs | Household surveyed | FSUs | Household surveyed |
| 92 | 1104 | 168 | 2014 |
| J&K-Urban | | | |
| Central sample | | State sample | |
| FSUs | Household surveyed | FSUs | Household surveyed |
| 70 | 840 | 135 | 1614 |

Sample Size

In J&K state, during 69th round 168 rural samples were covered and 2014 households were surveyed whereas in urban J&K, 135 samples were covered and 1614 households were surveyed.

CHAPTER-TWO

CHAPTER-2

Testing Poolability and Methodology for pooling

Testing Poolability of central and state sample

Though the central sample and state sample are drawn independently following identical sampling design with same concepts, definitions and instructions to collect the state sample data but due to lack of adequate training of field and processing staff of State/UTs, the data files in some cases are not properly validated. There is also expected agency bias in the two sets of data generated by different agencies. As such they cannot be merged for generating pooled estimate. Therefore one needs to test that the samples are coming from identical distribution function. Since the parametric distribution of the sample mean is unknown one may adopt non-parametric tests such as K-S test, Wald-Wolfowitz run test, Median test etc to test that the samples are coming from identical distribution function.

Median test

In statistics, the median test is a special case of Pearson's Chi-square test. It tests the null hypothesis that the medians of the populations from which two samples are drawn, are identical. Observations in each sample are assigned to two groups, one consisting of data whose values are higher than the median value in the two groups combined, and the other consisting of data whose values are at the median or below. A Pearson's Chi-square test is then used to determine whether the observed frequencies in each group differ from expected frequencies derived from a distribution combining the two groups. The statistical power of this test may sometimes be improved by using a value other than the median to define the groups say quintile classes— that is, by using a value which divides the groups into more nearly equal groups than the median would. This test is useful when the distributions of data differ markedly from normality, for example when raw scores have been arbitrarily classified into inappropriate ranges before being recorded such as size class of land possessed etc and often useful as an initial step of exploratory analysis of data.

Let m^* be the median of the pooled sample data. Construct 2×2 contingency table as below and use chi-square test if columns and rows are independent.

| Sample-type | no of sample observation | | Total |
|-----------------------|--------------------------|---------------|--------------|
| | $\leq m^*$ | $> m^*$ | |
| State Sample | N_{11} | N_{12} | $N_{1\cdot}$ |
| Central Sample | N_{21} | N_{22} | $N_{2\cdot}$ |
| Total | $N_{\cdot 1}$ | $N_{\cdot 2}$ | $N_{..}$ |

Wald-Wolfowitz run test

Suppose X and Y are independent random samples with cumulative distribution function (CDF) as $F_s(x)$ and $F_c(y)$. Null Hypothesis to be tested is $H_0: F_s(x) = F_c(x)$ for all x against alternative Hypothesis is $H_1: F_s(x) \leq F_c(x)$ for all x and $F_s(x) < F_c(x)$ for some x. Let x_1, x_2, \dots, x_m be iid observation from state sample with distributive function F_s and y_1, y_2, \dots, y_n be iid observation from central sample with distributive function F_c .

Pool the data and order them with respect to comparable characteristic under consideration say monthly per capita expenditure (MPCE). In the pooled order sequence put "1" for X and "0" for Y. Let U be the total runs observed where 'run' is a sequence of adjacent equal symbols.

For example, following sequence: 1111000111001111110000 is divided in six runs, three of them are made out of "1" and the others are made out of "0". The number of runs U is a random variable whose distribution for large sample can be treated as normal with:

mean:
$$\frac{2mn}{m+n} + 1$$

variance:
$$\frac{2mn(2mn - m - n)}{(m+n)^2(m+n-1)}$$

After normalizing the variable U one may use one sided z-test for testing the Null hypothesis. In extreme case the value of U will be 2 meaning by observed characteristic of all the observation of one sample is less than the other samples.

One of the limitations of this test is when there is a tie between two samples in the observed value. One has to resolve ties in usual manner. However if there is large number of ties which is bound to occur specially for qualitative attributes like education level etc, this test is not recommended. This test can be well applied for a continuous variable such as MPCE which are less prone to ties. For discrete variable chi-square test is recommended after suitably grouping the characteristic variable for getting adequate number of sample observation under each group.

Parametric test

Aggregate estimate: Let t_{yc} and t_{ys} be the estimate of Y based on central and state sample respectively with corresponding variances $V(t_{yc})$ and $V(t_{ys})$. For large sample, making all assumption of parametric test, one may use Z-Statistic to test the null hypothesis $H_0: E(t_{yc}) = E(t_{ys})$ where E stands for expectation.

$$Z = \frac{(t_{yc} - t_{ys})}{\sqrt{V(t_{yc}) + V(t_{ys})}}$$

$V(t_{yc})$ and $V(t_{ys})$ could be estimated when unknown as

$$\hat{V}(t_{yc}) = (t_{yd} - \hat{t}_{yc})^2 / 4, \quad \hat{V}(t_{ys}) = (t_{ysl} - \hat{t}_{ys})^2 / 4 \quad \text{based on sub-sample 1 \& 2 estimates.}$$

Estimate of rate: Let r_c and r_s be the estimate of population rates R_c and R_s ie Y/X based on central and state sample respectively with corresponding mean square error $MSE(r_c)$ and $MSE(r_s)$. For large sample, making all assumption of parametric test, one may use Z-Statistic to test the null hypothesis $H_0: E(r_c) = E(r_s)$ where E stands for expectation.

$$Z = \frac{(r_c - r_s)}{\sqrt{(MSE(r_c) + MSE(r_s))}}$$

$MSE(r_c)$ and $MSE(r_s)$ are estimated as follows:

$$\begin{aligned} MSE(r_c) &= (\hat{V}(t_{yc}) - 2 * r_c * \hat{Cov}(t_{yc}, t_{xc}) + r_c^2 * \hat{V}(t_{xc})) / t_{xc}^2 \\ MSE(r_s) &= (\hat{V}(t_{ys}) - 2 * r_s * \hat{Cov}(t_{ys}, t_{xs}) + r_s^2 * \hat{V}(t_{xs})) / t_{xs}^2 \end{aligned}$$

where

$$\hat{V}(t_{yc}) = (t_{yd} - \hat{t}_{yc})^2 / 4, \quad \hat{V}(t_{ys}) = (t_{ysl} - \hat{t}_{ys})^2 / 4$$

$$\hat{V}(t_{xc}) = (t_{xd} - \hat{t}_{xc})^2 / 4, \quad \hat{V}(t_{xs}) = (t_{xsl} - \hat{t}_{xs})^2 / 4$$

$$\hat{Cov}(t_{yc}, t_{xc}) = (t_{yd} - \hat{t}_{yc})(t_{xd} - \hat{t}_{xc}) / 4 \quad \text{based on sub-sample 1 \& 2 estimates.}$$

Methodology for pooling

Pooling by inverse weight of the variance of the estimates

Aggregate estimate: For any characteristic, consider the state sample (s) in the form of two independent sub-sample s1 and s2 and the central sample (c) in the form of two independent sub-sample c1 and c2. Based on this, the respective estimates for state and central can be computed as:

$$t_s = (t_{s1} + t_{s2})/2 \text{ and } t_c = (t_{c1} + t_{c2})/2$$

Pooled estimate leading to optimum combination of these two estimates is given by weighing with inverse of the variance of the estimate. Thus the pooled estimate is given by:

$$T_p = \frac{V(t_c)t_s + V(t_s)t_c}{V(t_c) + V(t_s)} \text{ with } V(T_p) = \frac{V(t_c)V(t_s)}{V(t_c) + V(t_s)}$$

In general $V(t_c)$ and $V(t_s)$ are unknown and can be estimated as

$$\hat{V}(t_c) = (t_{c1} - t_{c2})^2/4, \quad \hat{V}(t_s) = (t_{s1} - t_{s2})^2/4$$

Thus pooled estimate and estimate of pooled variance is given by

$$t_p = \frac{\hat{V}(t_c)t_s + \hat{V}(t_s)t_c}{\hat{V}(t_c) + \hat{V}(t_s)}, \quad \hat{V}(t_p) = \frac{\hat{V}(t_c)\hat{V}(t_s)}{\hat{V}(t_c) + \hat{V}(t_s)}$$

By virtue of weighing the two estimates at the domain level at which two estimates are pooled, the pooled estimate will always lie between the central and state sample estimates.

Estimate of rate: Let r_c and r_s be the estimate of R_c and R_s ie Y/X based on central and state sample respectively with corresponding estimated mean square error $mse(r_c)$ and $mse(r_s)$. The pooled estimate and estimate of variance of pooled ratio estimate may be given by:

$$r_p = \frac{mse(r_c)r_s + mse(r_s)r_c}{mse(r_c) + mse(r_s)}, \quad mse(r_p) = \frac{mse(r_c)mse(r_s)}{mse(r_c) + mse(r_s)}$$

Where $mse(r_c)$ and $mse(r_s)$ are calculated using formula given in para 4.1.4.2 above. Alternatively one can generate the pooled estimate of aggregate by inverse weight of estimate of variance obtained from central and state sample using formula given in para 4.2.1.1 for the characteristics x as well as y and obtain the pooled estimate of ratio as ratio of pooled estimate of aggregate. This will ensure consistency between pooled estimates of aggregate and the pooled estimate of ratio. Let t_{xp} and t_{yp} be the pooled estimate of aggregate for the parameter X and Y. The pooled estimate of R (i.e Y/X) is given by $r_p = t_{yp} / t_{xp}$ where $t_{yp} = atyc + btys$ and $t_{xp} = ct_{xc} + dt_{xs}$ and (a, b), (c, d) are the

estimated inverse variance weight pair of the characteristic x and y respectively. The estimated mse of pooled ratio estimate \hat{r}_p is given by:

$$\text{mse}(\hat{r}_p) = (\hat{V}(t_{yp}) - 2 \cdot \hat{r}_p \hat{\text{Cov}}(t_{yp}, t_{xp}) + \hat{r}_p^2 \hat{V}(t_{xp})) / \hat{t}_{xp}^2$$

where $\hat{V}(t_{yp}) = \frac{ab}{a+b}$, $\hat{V}(t_{xp}) = \frac{cd}{c+d}$ and

$$\hat{\text{Cov}}(t_{yp}, t_{xp}) = ac \hat{\text{Cov}}(t_{yc}, t_{xc}) + bd \hat{\text{Cov}}(t_{ys}, t_{xs}).$$

$$\hat{\text{Cov}}(t_{yc}, t_{xc}) = (t_{yd} - \bar{t}_{yc2})(t_{xd} - \bar{t}_{xc2})/4 \text{ based on sub-sample 1 & 2 estimates.}$$

$$\text{Similarly, } \hat{\text{Cov}}(t_{ys}, t_{xs}) = (t_{ysl} - \bar{t}_{ys2})(t_{xs} - \bar{t}_{xs2})/4$$

Method laid down in para 4.2.2.1 and 4.2.2.2 requires calculation of estimate of variance of the estimates before pooling them. Reliability of estimate of variance should be ascertained with due consideration of sample size. Besides complex calculations for each cell of the table, one needs to address issue of non-additivity of the component estimates with the estimate of total. For e.g. pooled estimate of MPCE of FOOD and NON-FOOD may not add up to MPCE of TOTAL. To obviate this problem one may generate the pooled estimates of components first and then derive the estimate of total as sum of estimates of components.

Pooling by simple average of the estimates

Many of the States are not fully equipped with complex calculation of estimate of variance especially when cells of the table contains ratio of two characteristics which is usually presented in the NSS reports. When the State's participation is equal matching of central samples, the simple average of two estimates may be a way of combining the estimates considering central and state samples as independent samples. The pooled estimate will always lie between the estimates based on central and state sample separately. Estimate of variance of estimate by Mahalanobis inter-penetrating sub sample method also becomes easier. Agency bias is also reflected in the estimated variance.

When the State's participation is of unequal matching of central samples, the weighted average of two estimates with weights being matching ratio of central and state sample may be a better way of combining the estimates considering central and state samples as independent samples. For any characteristic, consider the state sample (s) in the form of two independent sub-sample s1 and s2 and the central sample (c) in the form of two independent sub-sample c1 and c2. Let matching ratio of state and central sample be m : n. Based on this, the respective estimates for state and central can be computed as:

$$t_s = (t_{s1} + t_{s2})/2 \text{ and } t_c = (t_{c1} + t_{c2})/2$$

Pooled estimate of these two estimates is given by weighing with matching participation rate m:n.
Thus the pooled estimate is given by:

$$t_p = \frac{mt_s + nt_c}{m+n} \text{ with } V(t_p) = \frac{m^2 V(t_s) + n^2 V(t_c)}{(m+n)^2}$$

In general $V(t_c)$ and $V(t_s)$ can be estimated as $\hat{V}(t_c) = (t_{c1} - t_{c2})^2 / 4$,

$$\hat{V}(t_s) = (t_{s1} - t_{s2})^2 / 4 \text{ and thus } \hat{V}(t_p) = \frac{m^2 \hat{V}(t_s) + n^2 \hat{V}(t_c)}{(m+n)^2}$$

The pooled estimate will always lie between the estimates based on central and state sample separately.

Summing up: For those characteristics which are known to be distributed as Normal, poolability of the two sets of central and state data may be tested by standard parametric tests such as Z-test. For those characteristics for which transformation makes them Normal, such methodology may be adopted. In most of the situations where the distribution is non-normal and unknown, the two sets of data may be tested through various non-parametric tests such as those laid down in para 4.1 of the report. For discrete data, Standard tests of equality of proportions based on binomial distribution may be used and for multinomial distributions relevant chi-square tests may be used.
